Tempered glass is about four times stronger than Annealed glass.

Prior to tempering the glass, it is “shimmed” which is a light sanding process along all of the edges. This makes it easier to handle, but it can still have sharp edges. When in doubt wear gloves. Once tempered, if broken, under stress it will break into small granular chunks rather than the jagged shards that annealed glass will. Any cutting or grinding must be done prior to tempering.

While tempered glass is much stronger, the weak point is at the corners. So when handling tempered glass watch that you do not bump any of the corners.

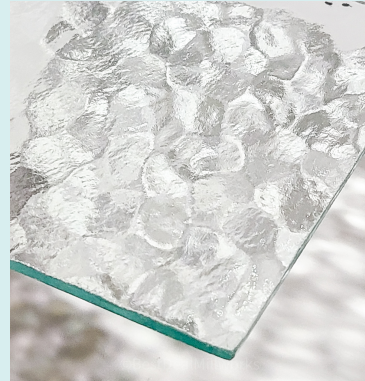

Tempered glass is used in high traffic areas, low windows and many other area where the likelihood of the glass breaking is higher; therefore reducing the likelihood of injury from broken glass.

Laminated glass is also a type of safety glass that consists of layers of plastic and toughened glass. In the event that laminated glass is broken, the shattered pieces are held in place by an interlayer that’s in between two or more layers of glass. The glass crumbles into small pieces but will remain bonded. The characteristic “spider web” shaped crack typically occurs in laminated glass. Laminated glass is most commonly used to produce vehicle windshields.
